

Figure A. Final mechanics-informed superconducting-network architecture

a

Six-device hierarchy

Nominal film force alone does not organize the transport outcomes.

Separated network fields

Local superconducting strength and weak-link transparency are distinct.

unresolved M0* sufficient structured support

c

b

Frozen multiscale architecture

Final frozen result: weak link connectivity dominant; spatial association = robust

Tested arrows: mechanics prior survives controls; weak-link role dominates; robustness passes.

d

Frozen scope and claim boundary

Manuscript phrasing: normalized mechanical-gradient structure is transport relevant, primarily through weak-link connectivity.

Caveat: this is a normalized forward-mechanics result, not an absolute device-specific strain reconstruction.
